### Abstract
CEACAM1 is a cell adhesion molecule. Alternative splicing of the Ceacaml gene generated two isoforms of CEACAM1, i.e. CEACAM1-L (long form) and CEACAM1-S (short form). We have shown that CEACAM1-L plays critical roles in prostate cancer progression. We propose to determine the function of CEACAM1 in prostate development, prostate homeostasis and prostate tumorigenesis by using gene targeting technologies. Specifically, we plan to generate mice with a targeted deletion of the CEACAM1 cytoplasmic domain. We have constructed aCeacaml targeting vector in which exons 7-9 of Ceacaml gene was flanked by loxP sites for the generation of conditional knockout of the Ceacaml gene. Embryonic stem cells containing the recombinant gene allele were established and injected into blastocysts for germ line transmission of the targeting construct. We have succeeded in producing mice harboring the conditional Ceacam1 knockout allele. In this extended period, we generated mice with homozygote conditional Ceacam1 allele and characterized the expression of CEACAM1 protein. In addition, we have crossed the homozygote conditional Ceacam1 mice with transgenic mice containing probasin-driven cre to generate mice with prostate-specific deletion of Ceacam1 gene. Initial analysis of 3 month old mouse prostates showed that deletion of Ceacam1-L in the mouse prostates led to epithelial hyperplasia.

INTRODUCTION

C-CAM1 (renamed as CEACAM1) is a cell adhesion molecule of the immunoglobulin supergene family (1). We have shown that CEACAM1 plays critical roles in prostate cancer initiation and progression and that loss of CEACAM1 is an early event in the development of prostate cancer (2). Although tumorigenesis studies in mouse xenograft model have suggested the involvement of CEACAM1 in epithelial cell growth and differentiation, the functional roles of CEACAM1 in normal prostate development, prostate homeostasis, and prostate tumorigenesis remain unclear. Towards the aim of unraveling the roles of CEACAM1’s growth suppressive activity in prostate growth and tumorigenesis, we propose to use gene targeting and embryonic stem cell technologies to generate CEACAM1 knockout mice. Specifically, we plan (1) to determine the roles of CEACAM1’s growth suppressive function in vivo by generating mice with a targeted deletion of the CEACAM1 cytoplasmic domain; (2) to determine the roles of CEACAM1’s growth suppressive function in prostate development and tumorigenesis by generating mice with a prostate-specific knockout of the CEACAM1 cytoplasmic domain. The proposed work was divided into two Tasks to be carried out in parallel.

Task 1. Generate mice with targeted deletion of CEACAM1 cytoplasmic domain to determine the roles of CEACAM1’s growth suppressive function in vivo (months 1-30)

Task 2. Prostate-specific loss of function of CEACAM1 gene in prostate (months 7-36)

Genetic manipulation of mouse genes in vivo is a powerful approach to understanding the function of a gene, both during embryonic development and in adult tissues. This method requires full knowledge of the genomic structure of the gene of interest. Unlike humans and rats, which each have one CEACAM1 gene, two CEACAM1-like genes, Ceacam1 and Ceacam2, were identified in mice. In the previous study, we have isolated and sequenced these two closely related Ceacam genes from a mouse 129 Sv/Ev library (3). We have also examined the tissue-specific and embryonic expressions of these mouse Ceacam1 and Ceacam2 genes (3). Our sequence analysis revealed that the genes encoded nine exons and spanned approx. 16-17 kb (Ceacam1) and 25 kb (Ceacam2). The genes were highly similar (79.6%). The major differences in the protein-coding regions were located in exons 2, 5 and 6. To determine whether
functional redundancy exists between Ceacam1 and Ceacam2, we examined their expression in 16 mouse tissues by using semi-quantitative reverse transcription-PCR. As in human and rat, in mouse Ceacam1 mRNA was highly abundant in the liver, small intestine, prostate and spleen. In contrast, Ceacam2 mRNA was only detected in kidney, testis and, to a lesser extent, spleen. In a mouse embryo, Ceacam1 mRNA was detected at day 8.5, disappeared between days 9.5 and 12.5, and re-appeared at day 19. On the other hand, no Ceacam2 mRNA was detected throughout embryonic development. The different tissue expression patterns and regulation during embryonic development suggest that the Ceacam1 and Ceacam2 proteins, although highly similar, may have different functions both during mouse development and in adulthood. Results from this study allow us to design a gene targeting strategy that is specific to Ceacam1 gene and also allow us to perform both straight and conditioned knockout of Ceacam1 gene in parallel.

We have designed a gene targeting strategy that is specific to Ceacam1 gene. In addition, the Ceacam1 gene in the targeting vector was flanked by loxP sites to allow for generation of both straight and conditional knockout of Ceacam1 gene. The targeting vector has been constructed and 24 embryonic stem cell clones containing the recombinant gene allele have been established. Two of the embryonic cell clones were injected into blastocysts for germ line transmission of the targeting construct toward the end of second funding period. In the final year of funding period, we have succeeded in producing mice harboring conditional Ceacam1 gene. Two founder mice from two embryonic cell clones showed germ line transmission of the targeting construct. Mice with homozygote conditional Ceacam1 allele were born from these two founder mice suggesting that embryonic lethality does not occur in mice carrying conditional Ceacam1 allele. We requested a one-year no cost extension to continue the project. In this extended one year, we generated sufficient mice with homozygote conditional Ceacam1 allele and characterized the expression of CEACAM1 protein in the wild-type and homozygote conditional Ceacam1 mice. In addition, we have further crossed the homozygote conditional Ceacam1 mice with transgenic mice containing probasin-driven cre (PB-Cre4) to generate mice with prostate-specific deletion of Ceacam1 gene. Initial analysis of 3-month-old mouse prostates showed that deletion of Ceacam1 in the mouse prostates led to epithelial hyperplasia. These results suggest that CEACAM1 has a critical role in prostate growth.
(5) BODY (Progress report)

Because Task 1 and Task 2 are performed in parallel, we describe the progresses in these aspects together.

5.1. Gene targeting strategy

Based on genomic characterization of Ceacam1 gene, we decided to delete the cytoplasmic domain of CEACAM1. This strategy is based on the following rationales: (1) the entire Ceacam1 gene, around 20 kb, is too large to delete; and (2) the cytoplasmic domain of CEACAM1 is critical for tumor suppression. A conditional knockout construct is designed to delete exons 7~9 in a tissue-specific or non-specific manner in the mice. ES cells harboring the targeting vector are injected into blastocysts to generate mice carrying the conditional Ceacam1 allele. For straight knockout, the goal of Task 1, the conditional knockout mice will be crossed with transgenic mice carrying actin-driven Cre recombinase, which is expressed during embryonic development. For conditional knockout, the goal of Task 2, the Ceacam1 gene will be deleted in prostate specifically by crossing the conditional knockout mice with transgenic mice carrying probasin-driven Cre recombinase. Thus, Task 1 and Task 2 are being performed in parallel. The gene knockout strategy is shown in Fig. 1.
Fig. 1. Maps of the Ceacam1 genomic locus and the loxP-targeting vector designed to introduce a Neo\textsuperscript{R} cassette. Exons are denoted by rectangles and loxP sites are denoted by triangles. Red rectangles indicate CEACAM coding regions. Successful targeting yields a conditional Ceacam1\textsuperscript{floxed} allele. Cre-mediated recombination results in deletion of Neo\textsuperscript{R} cassette and the cytoplasmic domain exons, yielding a knockout allele. Specific primers used to screen for various alleles are indicated by small arrows labeled a through c.
5.2. Targeting vector construction

A 129Sv/Ev mouse genomic library in BAC vectors was screened with a probe generated from cDNA coding for the full-length mouse CEACAM1. Three positive BAC clones were identified and their structures were determined by restriction mapping. Consistent with our previous study (3), two closely related genes, i.e. Ceacam1 and Ceacam2, were identified from restriction mapping. Based on tissue-specific and embryonic expression of Ceacam1 and Ceacam2 gene (3), we decided to delete the cytoplasmic domain of Ceacam1. A conditional knockout construct was designed to delete exons 7~9. The conditional targeting construct was designed by inserting a loxP-neo cassette at the Xmn1 site in intron 6 and a loxP fragment at the HindIII site in intron 9 of Ceacam1 (Fig. 1). The targeting vector includes 4.3 kb of homologous DNA upstream of the loxP-neo site and 3.4 kb of homologous DNA downstream of the second loxP site. The targeting vector was verified by restriction mapping.

5.3. Transfection and generation of embryonic stem cells harboring targeting vector

The targeting vector was transfected into embryonic stem cells by electroporation. A total of 270 ES cell clones were obtained from two electroporations. Genomic DNA was extracted from these ES cell clones. Half of the DNA from each sample was digested with SphI and processed for Southern blot analysis. The 5’ probe used is a 0.7kb Aпал/SpeI fragment from subclone BamHI-A. Using the 5’ probe, a ~9.2 kb band corresponding to the endogenous Ceacam1 and a ~10 kb band corresponding to Ceacam2 were detected in most samples. Many clones (a total of 24) included an additional hybridization signal at the size (8.1 kb) predicted for the homologous recombinant allele (Fig. 2). These potential positives clones were digested with Xho I and hybridized with the 3’ probe, which is a 1.2kb Sac I/Xho I fragment from subclone Apa I-4. A ~15.3 kb band corresponding to the endogenous allele of Ceacam1 and a ~17.1 kb band corresponding to recombinant allele were detected in 16 clones (Fig. 2). These 16 clones were also detected with a Neo probe, which gave a 17.1 kb band in Southern blot analysis. Taken together, a total of 16 ES cell clones containing the Ceacam1 conditional allele were generated. Three positive ES cell clones were injected into mouse blastocysts using procedures described in Chang et al. (4). Chimeric mice were obtained and they were mated with C57BL mice. The F1 mice having germ line transmission of the loxP-targeted Ceacam1 allele were interbred to generate F2 mice.
5.4. Genotyping of the wild-type and loxP-targeted (floxed) alleles

Germ line transmission was confirmed by PCR analysis. Isolated mouse tail DNA was used for PCR identification of the genotype. Three sets of primers that detect the wild-type and the floxed allele of Ceacam1, and the Ceacam2 gene were used to genotype the mice. Primer A (5' ACACAAGGAGGCCTCTCAGATGGCG 3') and Primer C (5'GCGCCTCCCCTACCCCGGTAGAATT 3'), containing sequences from Exon 6 of Ceacam1 and neomycin cassette, respectively, will produce a 488 bp PCR product from the floxed Ceacam1 allele. Primer A and Primer B (5' GACTTTGGCTTCCTGACTGGAGGA 3'), containing sequences from Intron 6, will generate a 382 bp PCR product from wild-type Ceacam1. Two founder mice from two embryonic cell clones showed germ line transmission of the targeting construct containing the conditional Ceacam1 gene. Mice with homozygous conditional Ceacam1 alleles were born from these two founder mice. These results suggest that embryonic lethality does not occur in the mice carrying conditional Ceacam1 knockout alleles, thus it is possible to pursue the function of CEACAM1 in normal prostate development, prostate homeostasis and prostate tumorigenesis in vivo.
5.5. CEACAM1 protein expression in wild-type and CEACAM1<sup>flox/flox</sup> mouse

To examine the effect of flox allele on the expression of CEACAM1 protein, we performed Western blot analysis on the tissue lysates prepared from prostates of wild-type and CEACAM1<sup>flox/flox</sup> mice. We found that the floxed CEACAM1 allele led to decreased expression of CEACAM1 protein (Fig. 4). Such a hypomorphic phenotype is commonly seen in loxP-targeted allele. Previous studies have established that there are two alternatively spliced form of CEACAM1, i.e. CEACAM1-L (long form) and CEACAM1-S (short form). Because only CEACAM1-L has tumor suppressive activity, our gene targeting strategy was to delete the cytoplasmic domain of CEACAM1-L. We examined the effect of the conditional Ceacam1 allele on the expression of CEACAM1-L and CEACAM1-S. Due to the glycosylation of CEACAM1, the presence of CEACAM1-L and CEACAM1-S, which have molecular mass difference of 7 kDa, cannot be resolved well in SDS-PAGE directly. We thus assessed the amount of CEACAM1-L and CEACAM1-S in the wild-type and CEACAM1<sup>flox/flox</sup> mice by treating the tissue lysates with PNGase to remove N-linked glycosylation. As shown in Fig. 4, CEACAM1-L and CEACAM1-S are present in both wild-type and CEACAM1<sup>flox/flox</sup> cell lysates. However, only CEACAM1-L showed significant decrease in CEACAM1<sup>flox/flox</sup> mice when compared with those in wild-type mice.
5.6. Effect of cre-recombinase on Ceacam1 conditional allele.

We test whether the loxp sites that flank exons 7, 8, and 9 of Ceacam1 allele can be removed by cre recombinase by using recombinant adenovirus with cre gene (Ad-Cre). CEACAM1\textsuperscript{flox/flox} mice were treated with Ad-Cre or control adenovirus Ad-gal (containing beta-galactosidase gene) by i.v. injection of adenovirus. Western blots were performed on the cell lysates prepared from livers of these mice at 21 days post-injection. As shown in Fig. 5, there is a significant decrease in the level of CEACAM1-L in the mouse treated with Ad-Cre. This
observation suggests that exons 7-9 of Ceacam1 can be removed by treatment of CEACAM1\textsuperscript{flox/flox} mice with cre recombinase.

5.7. Generation of prostate-specific deletion of Ceacam1 by crossing CEACAM1\textsuperscript{flox/flox} mice with PB-Cre4 mice

To generate mice with prostate-specific deletion of Ceacam1, we crossed the CEACAM1\textsuperscript{flox/flox} mice with the transgenic mouse (PB-cre4) from NIH mouse consortium. PB-cre4 mice is a transgenic mouse line containing cre under the ARR2PB promoter. ARR2PB is a third generation probasin promoter that has been designed to target high levels of transgene expression specifically to the prostate. This new composite PB promoter construct (ARR2PB) is less than 500 bp in size, but is androgen and glucocorticoid regulated and prostate-specific, and it can target high level expression of a protein in the prostate of the transgenic mice (5). CEACAM1\textsuperscript{flox/flox} mice containing cre allele was confirmed by PCR analysis. Isolated mouse-tail DNA was used for PCR using primer Cre-F (5’ ttgcctgcattaccggtcgatgca 3’) and Cre-R (5’
gatctggaatctggctat 3') and the PCR product is 500 bp. Male mice homozygote with Ceacam1 floxed allele with (Ceacam1^{flox/flox},cre+) and without (Ceacam1^{flox/flox},cre-) cre were selected for phenotype analysis. We have obtained two mice each with the specific genotype. Because probasin promoter becomes active at 5-7 weeks after birth, we killed these mice at the age of three months and the prostates were collected and analyzed. As shown in Fig. 6, prostates from mice without cre transgene showed relatively normal morphology. In the mice with cre transgene, there was a decrease in the size of the luminal epithelial cells and these cells seem to be less differentiated compared to the prostates from mice without cre. The morphological changes were observed in both ventral prostate and dorsal prostate. We are expanding these mouse colonies to characterize the effect of loss of CEACAM1-L on prostate.

![Fig. 6. Morphology of dorsal prostates.](image)

(6) KEY RESEARCH ACCOMPLISHMENTS

- Designed a knockout strategy that allows Task1 and Task2 to be carried out in parallel.
- Constructed the targeting vector.
- Transfected the targeting vector into embryonic stem cells and selected 24 positive ES cell clones.
- Injected three ES cell clones into blastocysts.
❖ Bred and genotyped mice for the presence of recombinant allele.
❖ Obtained mice carrying heterozygote and homozygote recombinant allele.
❖ Analyzed the expression of CEACAM1 protein in mice carrying floxed Ceacam1 allele to test for the effect of floxed allele on CEACAM1 protein expression
❖ Analyzed the effect of cre recombinase on the floxed exons.
❖ Cross the mice with homozygote Ceacam1 floxed allele with transgenic mice carrying probasin promoter driven cre gene.
❖ Analyzed the prostate phenotype of mice homozygote with Ceacam1 floxed allele with and without probasin-driven cre transgene.

(7) REPORTABLE OUTCOMES

(8) CONCLUSION We propose to determine the roles of CEACAM1's growth suppressive activity in prostate growth and tumorigenesis by using gene targeting and embryonic stem cell technologies to generate knockout mice. We have designed and constructed a gene targeting vector for specific disruption of the Ceacaml gene. This gene targeting strategy will allow us to perform both straight and conditioned knockout of Ceacam1 gene in parallel. Embryonic stem cells containing the knockout construct were generated and injected into blastocysts. We have succeeded in generating mice carrying Ceacam1 conditional knock out allele. We found that the recombinant allele alters the endogenous Ceacam1 expression level. Deletion of the C-terminal portion of Ceacam1 gene in the mouse prostate by probasin promoter driven cre gene resulted in less differentiated luminal epithelial cells in the mouse prostate at 3 month of age.

D. Anderson Cancer Center, Houston, TX 77030, U.S.A.

The intercellular adhesion molecule CEACAM1, also known as C-CAM1 (where CAM is cell-adhesion molecule), can function as a tumour suppressor in several carcinomas, including those of the prostate, breast, bladder and colon. This suggests that CEACAM1 may play an important role in the regulation of normal cell growth and differentiation. However, there is no direct evidence to support this putative function of CEACAM1. To elucidate its physiological function by targeted gene deletion, we isolated the Ceacam genes from a mouse 129 Sv/Ev library. Although there is only one Ceacam1 gene in humans and one in rats, two homologous genes (Ceacam1 and Ceacam2) have been identified in the mouse. Our sequence analysis revealed that the genes encoded nine exons and spanned approx. 16–17 kb (Ceacam1) and 25 kb (Ceacam2). The genes were highly similar (79.6%). The major differences in the protein-coding regions were located in exons 2, 5 and 6 (76.9%, 87.0% and 78.5% similarity respectively). In addition, introns 2, 5 and 7 were also significantly different, being 29.7%, 59.8% and 64.5% similar respectively. While most of these differences were due to nucleotide substitutions, two insertions of 418 and 5849 bp occurred in intron 2 of Ceacam2, and another two insertions of 1384 and 197 bp occurred in introns 5 and 7 respectively. To determine whether functional redundancy exists between Ceacam1 and Ceacam2, we examined their expression in 16 mouse tissues by using semi-quantitative reverse transcription–PCR. As in human and rat, in the mouse Ceacam1 mRNA was highly abundant in the liver, small intestine, prostate and spleen. In contrast, Ceacam2 mRNA was only detected in kidney, testis and, to a lesser extent, spleen. Reverse transcription–PCR using testis RNA indicated that Ceacam2 in the testis is an alternatively spliced form containing only exons 1, 2, 5, 6, 8 and 9. In the mouse embryo, Ceacam1 mRNA was detected at day 8.5, disappeared between days 9.5 and 12.5, and re-appeared at day 19. On the other hand, no Ceacam2 mRNA was detected throughout embryonic development. The different tissue expression patterns and regulation during embryonic development suggest that the CEACAM1 and CEACAM2 proteins, although highly similar, may have different functions both during mouse development and in adulthood.

Key words: C-CAM, cell-adhesion molecule, gene expression, tumour suppressor.

INTRODUCTION

The intercellular adhesion molecule CEACAM1, also known as C-CAM1 [1] (where CAM is cell-adhesion molecule), is a member of the Ig gene family [2]. In addition to its cell-adhesion function, CEACAM1 is also a tumour suppressor in prostate [3], breast [4], bladder [5] and colon [6] carcinomas. Consistent with its role as a tumour suppressor, loss of CEACAM1 expression was observed in hepatomas [7], colon carcinomas [8–10] and endometrial [11] and prostate [12,13] cancers. This suggests that CEACAM1 may regulate cell growth and differentiation.

To elucidate the physiological functions of CEACAM1, we plan to generate mice with targeted Ceacam deletions. Genetic manipulation of mouse genes in vivo is a powerful approach for understanding the function of a gene, both during embryonic development and in adult tissues. This method requires full knowledge of the genomic structure of the gene of interest. Unlike humans and rats, which each have one Ceacam1 gene [14–16], two Ceacam1-like genes, Ceacam1 and Ceacam2, were identified in BALB/c mice [17]. This poses potential problems in any attempt to manipulate these genes. First, if the two genes have the same function, deletion of one gene may not produce any phenotypic alteration. Secondly, if there is no significant difference in the sequences of the genes, any genetic manipulation may not be specific for a single gene, or it might be difficult to ascertain which gene was altered. It is, therefore, essential to determine the complete sequences and expression profiles of these related Ceacam genes in the 129 Sv mouse strain before genetic manipulation is performed.

We report herein the isolation and sequencing of the full-length mouse Ceacam1 and Ceacam2 genes. They both encode nine exons, with significant sequence differences in certain regions. These sequence differences will allow selective targeting of one Ceacam gene compared with another. In addition, the tissue-specific distributions of CEACAM1 and CEACAM2 were different, and only Ceacam1 was expressed during embryonic development. The differences in their tissue and developmental expression patterns suggest that these two genes may have different functions in vivo.

MATERIALS AND METHODS

Isolation and characterization of Ceacam1 and Ceacam2

A 129 Sv/Ev mouse genomic library in ALEX (provided by Dr Li-Yuan Yu-Lee, Baylor College of Medicine, Houston, TX, 77030, U.S.A.) has been screened with a probe spanning the Ceacam3 gene. The resulting clones were sequenced and characterized.

Abbreviations used: CAM, cell-adhesion molecule; RT-PCR, reverse transcription–PCR.

© 2001 Biochemical Society
U.S.A.) was screened with the 1.6 kb full-length mouse Ceacam1 cDNA [18], which had been labelled by using the Klenow fragment of DNA polymerase I, random hexamericotide primers and [α-32P]dCTP [19]. A total of 24 positive clones were identified in the initial screening of this genomic library. PCR with Oligo 127 (5'-GGTGTACCTAGGCTACAGGAAT-3') and Oligo 122 (5'-GAAGGCAGCCTAGTGTCTGCTG-3'), which are specific to the 5' region of mouse Ceacam1 [20], showed that seven of the clones had the N-terminal Ceacam1 sequence. Similarly, PCR with Oligo 120 (5'-GAAGTCTGGGGATCTGGCTCCTT-3') and Oligo 131 (5'-TGGAAAATTCAGGACAAGTGATATCG-3') showed that seven clones had the 3' Ceacam1 sequence. These clones were isolated by secondary and tertiary screening and characterized by restriction mapping. The nucleotide sequences of the exons and introns were determined by primer walking using specific oligonucleotide primers. Sequencing was performed by the DNA Sequencing Core Facilities at M. D. Anderson Cancer Center with an automated fluorescent DNA sequencer (Applied Biosystems Inc., Ramsey, NJ, U.S.A.).

Analysis of Ceacam1 and Ceacam2 expression using a mouse cDNA panel

A mouse cDNA panel containing first-strand cDNA prepared from mouse tissues and normalized for β-actin expression was purchased from Orgene Technologies Inc. (Rockville, MD, U.S.A.) and used to analyse the expression of Ceacam1 and Ceacam2 in various mouse tissues. Oligonucleotides specific to exon 1 of Ceacam1 (Oligo 116, 5'-AACATGCCCCTGGCCTCTTTTT-3'); Oligo 179, 5'-AAATGCACAGTCGCCGTTGAGCC-3'; and to exon 2 of Ceacam2 (Oligo 117, 5'-AAATATGAATGAAAGGAGATCTGAGTACG-3') and Oligo 180, 5'-AAATGTCCAAGGACCACCT CCTACG-3') were used as primers to detect specific mRNAs for Ceacam1 and Ceacam2 by PCR. PCR cycling conditions were as follows: (1) pre-denaturation (94 °C, 3 min) for one cycle; (2) denaturation (94 °C, 30 s), annealing (60 °C, 30 s) and extension (72 °C, 2 min) for 35 cycles; and (3) final extension (72 °C, 5 min). The predicted size of the PCR products was 246 bp. These PCR products were analysed by agarose-gel electrophoresis, transferred to a nylon membrane and hybridized with [32P]-labelled oligonucleotide probes specific to Ceacam1 (Oligo 181; 5'-AACACACGAATAAGCAGACCTGCT-3') and Ceacam2 (Oligo 182; 5'-TCTCTAGCTCAGGACAATGCT-3').

Ceacam2 cDNA sequence from mouse testis

RNA was prepared from mouse testis by using RNAzol B (TEL-TEST Inc. Friendswood, TX, U.S.A.). The cDNAs coding for Ceacam2 were obtained from the testis RNA by reverse transcription–PCR (RT-PCR) with Oligo 630 (5'-GAATTTCAAGCTTAAAGATCAGGAGCACAC-3'), which contains nucleotides -36 to +1 of exon 1, and Oligo 631 (5'-GCCGCCGCTGCTGGATGATGATGATGATGATGATGATGGCTCTCTTCTCTAGAATAAC-3'), which is complementary to the end of the coding sequence in exon 9 plus seven histidine codons. RT-PCR was performed with Oligo 630 and Oligo 631 according to the procedures provided by the manufacturer (Amersham/Pharmacia Corp., Arlington Heights, IL, U.S.A.). The PCR product was subcloned into pCR1-topo (Invitrogen, San Diego, CA, U.S.A.) and its sequence was determined.

RESULTS

Isolation and characterization of mouse Ceacam1 and Ceacam2 genes

The seven clones with the 5' sequence of Ceacam1 had different restriction maps, as did another seven clones with the 3' end. The different restriction maps seemed to reflect different genes. Grouping these clones according to their restriction maps and DNA sequences revealed two distinct sequences, representing Ceacam1 and Ceacam2. The overlapping genomic clones that spanned Ceacam1 and Ceacam2 are shown in Figure 1. DNA sequence analysis of both strands of these two genes revealed that Ceacam1 and Ceacam2 each contain nine exons each, with sizes of approx. 18.3 and 24.65 kb respectively (Figure 1).

The sizes of the exons and introns and the intron/exon boundary sequences for Ceacam1 and Ceacam2 are shown in Tables 1 and 2 respectively. The first exon, which codes for the first two-thirds of the signal sequence, is 304 bp in both Ceacam1 and Ceacam2. In contrast, exons 2-9 are each approx. 300 bp, and each codes for one Ig-like domain in both Ceacam1 and Ceacam2. The transmembrane domain is encoded by exon 6 and the cytoplasmic domain by exons 7-9. Consistent with the RNA splicing rule [21], each intron starts with GT at the 5' end and ends with AG at the 3' end (Tables 1 and 2).

Comparison of Ceacam1 and Ceacam2 genes

The overall similarity between Ceacam1 and Ceacam2, including all exons and introns, is approx. 79.6%. The similarities between Ceacam1 and Ceacam2, including all exons and introns, is approx. 79.6%.

Expression of Ceacam1 and Ceacam2 mRNAs in mouse tissues

Oligonucleotides for PCR analyses are underlined. Oligonucleotides for hybridization (Oligo 181 and Oligo 182) are boxed. The nucleotides are numbered with the A of the start ATG as the first nucleotide according to the genomic sequence. The amino acids are numbered with the start methionine (ATG) as the first amino acid.

The exons and introns of Ceacam1 and Ceacam2 are shown in Table 3. The major differences between these two genes are in exon 2, intron 2, intron 5, exon 6 and intron 7, which are 76.9%, 29.7%, 59.8%, 78.5% and 64.5% similar respectively. The nucleotide and the deduced amino acid sequences of exon 2 for Ceacam1 and Ceacam2 are shown in Figure 2. It is apparent that most of the sequence substitutions in exons 2, which code for the first Ig domain, do result in amino acid substitutions in Ceacam1 and Ceacam2. Thus the amino acid identity between the first Ig domains of CEACAM1 and CEACAM2 is 57.1%, which is significantly lower than the similarity of other domains. In addition, insertions of 418 bp and 5849 bp in intron 2, and of 1384 bp and 197 bp in introns 5 and 7 respectively, are found in Ceacam2 compared with Ceacam1 (Table 3 and Figure 1C).

Expression of Ceacam1 and Ceacam2 mRNAs in mouse tissues

To determine the tissue-specific distribution of Ceacam1 and Ceacam2, we performed semi-quantitative RT-PCR on a panel of mouse cDNAs from various tissues by using Ceacam1- and Ceacam2-specific oligonucleotide pairs. The PCR products were hybridized further with Ceacam1- and Ceacam2-specific oligonucleotides derived from exon 2, the least similar exon (Figure 2). The specificities of these two oligonucleotides were confirmed by Southern blot analysis. As shown in Figure 3(A), Oligo 181 hybridized to DNA from A3 (Ceacam1) but not from A13 (Ceacam2), whereas Oligo 182 only hybridized to A13 DNA. Both Ceacam1 and Ceacam2 mRNAs were detected, although not in the same tissues. This observation supports the notion that both Ceacam1 and Ceacam2 are expressed in mouse (Figures 3B and 3C). High levels of Ceacam1 mRNA were detected in liver, small intestine, prostate and spleen (Figure 3B), similar to the tissue expression pattern in humans [22] and rats [23,24]. Ceacam1 mRNA was also detected in heart, kidney, stomach, muscle, skin and uterus. In contrast, Ceacam2 mRNAs were detected only in kidney, testis and, to a lesser extent, spleen (Figure 3C). These
Differential expression of mouse Ceac1 and Ceac2 genes

The expression of Ceac1 and Ceac2 was examined in mouse embryos at days 8.5, 9.5, 12.5 and 19 of embryonic development by RT-PCR hybridization as described above. Using Ceac1-specific Oligo 181, we observed age-related differences in mRNA levels: we detected the mRNA at day 8.5, it had disappeared at days 9.5–12.5, and it re-appeared at day 19 (Figure 5A). In contrast, no hybridization signal was detected when Ceac2-specific Oligo 182 was used (Figure 5B). This result suggests that the expression of Ceac1, but not that of Ceac2, is developmentally regulated.

DISCUSSION

Because targeted gene deletion is performed in the 129 Sv mouse, we determined in the present studies the complete genomic structure and DNA sequences of the mouse Ceac1 and Ceac2 genes in a 129Sv/Ev mouse genomic library. We also examined the expression patterns of these two genes in adult mouse tissues and during embryonic development. Several conclusions can be made from this study. First, the Ceac1 and Ceac2 genes contain sufficient sequence differences that targeted gene deletion specific to either gene should be feasible. Secondly, functional redundancy may not be a problem when only one of these two genes is deleted, because, although Ceac1 and Ceac2 genes are highly homologous, they have different tissue expression patterns. Thirdly, Ceac1 is probably more important than Ceac2 in the mouse, because the tissue expression pattern of Ceac1 is similar to those of the single Ceacam genes in humans and rats. Conservation of the expression profile among these different species suggests that the function of Ceacam2 cDNA

Although it was detected in testis, kidney and spleen, Ceacam2 mRNA may not contain open reading frames for protein translation. As testis expressed only Ceacam2, the cDNAs coding for Ceacam2 were obtained from testis RNA by RT-PCR with Oligo 630, which contained the 5' untranslated region of exon 1, and Oligo 631, complementary to the exon 9 coding region at the termination codon TGA. The 1 kb PCR product obtained only hybridized to Ceacam2-specific Oligo 182, and not to Ceacam1-specific Oligo 181, suggesting that the fragment codes for Ceacam2. This result is consistent with the tissue distribution of Ceacam2 (Figure 3C). The PCR product was then subcloned and its sequence was determined (Figure 4). The mouse testis cDNA contained exons 1, 2, 5, 6, 8 and 9, and had an open reading frame of 273 amino acids (Figure 4B).

Markers sizes are indicated by thin arrows, and the size of the PCR product is indicated by thick arrow.

Expression of Ceacam1 and Ceacam2 during mouse embryonic development

The expression of Ceacam1 and Ceacam2 was examined in mouse embryos at days 8.5, 9.5, 12.5 and 19 of embryonic development by RT-PCR hybridization as described above. Using Ceacam1-specific Oligo 181, we observed age-related differences in mRNA levels: we detected the mRNA at day 8.5, it had disappeared at days 9.5–12.5, and it re-appeared at day 19 (Figure 5A). In contrast, no hybridization signal was detected when Ceacam2-specific Oligo 182 was used (Figure 5B). This result suggests that the expression of Ceacam1, but not that of Ceacam2, is developmentally regulated.

and its sequence was determined (Figure 4). The mouse testis cDNA contained exons 1, 2, 5, 6, 8 and 9, and had an open reading frame of 273 amino acids (Figure 4B).

DISCUSSION

Because targeted gene deletion is performed in the 129 Sv mouse, we determined in the present studies the complete genomic structure and DNA sequences of the mouse Ceacam1 and Ceacam2 genes in a 129Sv/Ev mouse genomic library. We also examined the expression patterns of these two genes in adult mouse tissues and during embryonic development. Several conclusions can be made from this study. First, the Ceacam1 and Ceacam2 genes contain sufficient sequence differences that targeted gene deletion specific to either gene should be feasible. Secondly, functional redundancy may not be a problem when only one of these two genes is deleted, because, although Ceacam1 and Ceacam2 are highly homologous, they have different tissue expression patterns. Thirdly, Ceacam1 is probably more important than Ceacam2 in the mouse, because the tissue expression pattern of Ceacam1 is similar to those of the single Ceacam genes in humans and rats. Conservation of the expression profile among these different species suggests that the function of
Ceacam1 may be essential. Fourthly, Ceacam2 plays no role in embryonic development; it is not expressed in the mouse embryo.

The results of the present study provide important information for the design of gene targeting strategies for functional studies of Ceacam genes, by either deleting or introducing mutations into the Ceacam genes in the mouse germline. The differences in the two DNA sequences can be used to target a specific gene. As Ceacam1 lacks the 418 and 5849 bp insertions in Ceacam2 intron 2 and the 1384 bp insertion present in Ceacam2 intron 5 (Figure 1C), gene-targeting vectors containing introns 2 or 5 of Ceacam1 or Ceacam2 could be used to achieve selective homologous recombination in the desired gene. If mutant mice in which only one Ceacam gene is deleted survive, then they can be crossed further to generate mice deficient in both Ceacam genes. However, as Ceacam1 and Ceacam2 are both on chromosome 7, it is possible that they are too close to allow construction of double-gene-knockout mice by crossing the single-gene-knockout mice.

The existence of the highly similar second Ceacam gene, Ceacam2, in mice raises the possibility that Ceacam2 is a pseudogene. However, our results indicate that Ceacam2 is probably not a pseudogene, since (1) Ceacam2 contains a complete set of exons and introns typical of a Ceacam gene; (2) Ceacam2 is transcribed in mouse, as shown by the presence of Ceacam2 mRNA in several tissues; and (3) Ceacam2 mRNA contains an open reading frame of 273 amino acids in testis, as has been shown in CMT-93 mouse rectal carcinoma cells [17]. These findings raise the interesting question of the function of Ceacam2. One of the functions of CEACAM1 is inhibition of tumour growth [3,6]. This suggests that this protein may play an important role in regulating cell growth and differentiation. Structural and functional analyses of rat CEACAM1 have revealed that the tumour-suppressive function requires a long cytoplasmic domain, generated by alternative splicing [4,6,24]. Because the cytoplasmic domains of CEACAM1 and CEACAM2 are identical, CEACAM2 may also have growth-suppressive activity. However, the role of CEACAM2 in testis, which is composed of rapidly dividing cells in spermatogenesis, is not clear. Thus the in vivo function of CEACAM2 may not be revealed until its gene is deleted in the mouse.

Knocking out a gene may have no phenotypic effect if related genes have similar functions. We showed that Ceacam1 and Ceacam2 are expressed in different tissues in the mouse. Ceacam1 mRNA was detected in tissues rich in epithelial cells, which is consistent with expression of the CEACAM1 homologue in rats and humans [25–27]. In contrast, Ceacam2 mRNA was abundantly expressed in testis, which does not express Ceacam1 mRNA. In addition, Ceacam2 mRNA was undetectable in the mouse embryo, whereas Ceacam1 mRNA was developmentally regulated. Thus it appears that the two mouse Ceacam genes are not functionally redundant. However, we cannot rule out the possibility that the loss of Ceacam1 expression may up-regulate expression of Ceacam2. These studies will have to await targeted gene deletion of these two related genes.
